

### \*\*\*How to install and run instruction\*\*\*

To use the application it will be necessary to have a Postgresql database created with your desired name, following that step it will be necessary to create the .env file with the data to access it user, password, host, port and database name.

With the Database setup complete we can start installing the python requirements , make sure the terminal is in the folder containing the project and run the following pip command *pip install -r requirements.txt*. After installing we are ready to run the project!

If you don't have the csv's provided start by running the file *generate\_csv.py* this will create all the mock data necessary to test the project. In sequence run the *load\_data.py* file ,**remember this will drop everything you had in the database!**, this file shapes the database structure and inserts the mock data stored in the csv's. The last file we will run is the *api.py* file keep it running in the background as you test the project.

To test the project you'll need Postman, open the program and import the json stored in the folder *postman\_collection* this file contains the requests needed as well as the requirements to use them. Just run and everything should be working!!
